Essential oil of *Cordia millenii* from Nigeria

Opeyemi N Avoseh, Isiaka A Ogunwande, Peter O Afolabi, Oladipupo A Lawal, Tran D Thang, Roberta Ascrizzi and Flamini Guido

**Abstract**

*Cordia millenii* Bak. (Boraginaceae) is used in the south-western Nigeria to cure ache and pain disorders. Essential oil was obtained by hydrodistillation of air dried leaves of *C. millenii* in a Clevenger-type apparatus. The yield of the essential oil was 0.026% (v/w), calculated on dry weight basis. The chemical constituents of the oil were analyzed by gas chromatography (GC) and gas chromatography-mass spectrometry (GC-MS) on HP-5 column. The major constituents of the essential oil were limonene (19.9%), diallyl disulfide (18.4%), β-caryophyllene (16.6%), linalool (13.4%) and nonanal (10.6%). The anti-nociceptive property of the essential oil was statistically non-significant (p>0.05) when compared to the control for most concentrations except at 120th mins (p<0.05) for 200 mg p.o. The 200-mg p.o. dose only displayed anti-inflammatory activity at the 1st h (p<0.01) with others non-significant (p>0.05). This is the first report of the chemical composition and biological activities of the essential oils of *C. millenii*.

**Keywords:** *Cordia millenii*, terpenes, anti-nociceptive activity anti-inflammatory activity

1. Introduction

From time immemorial, smokes from the medicinal plants have been in use by humans for the treatment of different diseases. It was a common practice in many cultures and among famous ancient physicians. The records, written on clay tablets (from Mesopotamia dated about 2600 BC) are still in use as references for the treatment different ailments ranging from coughs and colds to parasitic infections and inflammations [1]. Plant derived smoke has multiple uses, including air purification, flavoring, medicinal, seed germination, pest control, preservation, religious and veterinary among other historical and modern applications [2].

1.2 *Cyperus esculentus* (Tiger nut)

*Cordia millenii* (Bak.) is a medicinal plant belonging to Boraginaceae family. It is widely distributed in tropical Africa. The plant can grow to a height of 60 to 100 ft, bole cylindrical, but rarely straight, 30 to 40 ft. in length; trunks about 3 ft in diameter above buttresses [1]. The plant has been used in ethnomedicine for the treatment of fever, cough, stomachache, mild tonic, astringent, toothache and inflammation related disorders. Extracts from *C. millenii* have shown the antifertility [1], antimicrobial [3] and antioxidants [2] effects. In addition, the extracts have prevented lipopolysaccharide-induced neuroinflammation [3]. The phytochemical compounds previously isolated from the plant include cordiachromes A–F [4]. Until now, no information is available on essential oils of *C. millenii*. This paper describes for the first time, the chemical composition and observed anti-inflammatory actions of *C. millenii* essential oil. Recently, we have published data on the chemical constituents, anti-inflammatory and anti-nociceptivel activities of essential oils from Nigerian plants [5-7].

2. Materials and methods

2.1 Drugs and chemicals

Carrageenan drug of analytical grade was obtained from Sigma-Aldrich Chemical Co. (St Louis, MO, USA). Ibuprofen injection (May and Baker) and Diclofenac Injection (Dizpharm, Nigeria Ltd.) were purchased from Lagos State University Pharmacy.

2.2 Collection of plant

The leaves of *C. millenii* were collected from Ayetoro, Ilesha (7°37′0N 4°43′0E), Osun State in June 2017. Botanical identification was achieved by Mr. Dotanus E. of Herbarium, Department of Botany, University of Ibadan, Nigeria. A voucher specimen (UIH-22607) was
deposited at the herbarium. The leaves were air-dried under laboratory shade (27 °C) for two weeks.

2.3 Hydrodistillation of essential oil
Two hundred and sixty grams of the air-dried and pulverized leaves of *C. millenii* was used. The essential oil was obtained by hydrodistillation which was carried out in an all-glass Clevenger-type distillation as reported previously [5-7].

2.4 Analysis of oil sample
Gas chromatography (GC) analysis was accomplished with a HP-5890 Series II instrument equipped with a HP-Wax and HP-5 capillary columns (both 30 m × 0.25 mm, 0.25 μm film thickness), working with the following temperature program: 60°C for 10 min, rising at 5°C/min to 220°C. The injector and detector temperatures were maintained at 250°C; carrier gas nitrogen (2 mL/min); detector dual, FID; split ratio 1:30. The volume injected was 0.5 μL. The relative proportions of the oil constituents were percentages obtained by FID peak area normalization without the use of a response factor. Gas chromatography-mass spectrometry (GC-EIMS) analysis was performed with a Varian CP-3800 gas-chromatograph equipped with a HP-5 capillary column (30 m x 0.25 mm; film thickness 0.25 μm) and a Varian Saturn 2000 ion trap mass detector. Analytical conditions: injector and transfer line temperature 220°C and 240°C, respectively; oven temperature programmed from 60°C-240°C at 3°C/min.; carrier gas helium at a flow rate of 1mL/min.; injection volume 0.2 μL (10% n-hexane solution); split ratio 1:30. Mass spectra were recorded at 70 eV. The acquisition mass range was m/z 30-300 at a scan rate of 1 scan/sec.

The identification of the constituents was based on comparison of the retention times with those of authentic samples, comparing their linear indices relative to a series of *n*-alkanes. Further identifications were also made possible by the use of a homemade library of mass spectra built up from pure substances and components of known oils, and MS literature data as described previously [5-7]. Moreover, the molecular weights of all the identified substances were confirmed by GC-CIMS, using MeOH as CI ionizing gas.

2.5 Study Animals
Eight-week-old Wistar rats of average weight of 150 to 200 g of either sex were bought and kept in the animal house of the Department of Biochemistry, Lagos State University, Nigeria. Standard conditions of temperature (23 ± 2°C), light accessibility (12 h light and darkness cycle) with free access to standard pellet feed, tidy environment and water *ad libitum*. All experimental procedures were approved under the Lagos State University Research Ethical Clearance Committee (RECC) of the University (Approval no: 012/2017/LASU/BCH).

The animals were assigned at random to a group of 5 consisting of 5 animals per group: Group 1- Control group (SALine solution); Group 2- Diclofenac treated group 100 mg/kg (Standard Group); Group 3- 100 mg/kg of *C. mellini* essential oils; Group 4- 200 mg/kg of essential oil; and Group 5- 400 mg/kg of essential oil. All treatments were administered orally using the canula syringe.

2.6 Carrageenan-induced rat paw edema (Anti-inflammatory test)
Carrageenan induced rat paw edema was done according to a modification form of an established procedure [8,9]. Twenty-five Wistar rats (both sexes, 150-200 g each) divided into 5 animals in each groups used for study, induced by subcutaneous injection of a 0.1 ml of 1% freshly prepared carrageenan in saline in the right hind paw of rats and 1mL of the vehicle were administered for all doses. Paw volume of the injected rats was measured every hour for 4 h using a plethysmometer (Ugo Basile, Italy).

2.7 Hot plate test for anti-nociceptive study
The experiment was carried out according to the modified method [10]. Twenty (25) mature Wistar rats both sexes were randomly divided into 5 groups of 5 rats per group. The animals were fasted for 12 h with provision of clean water *ad libitum*. Each rat was placed upon the heated metal plate (hot plate) maintained at the temperature of about 50-55°C within the restraining glass cylinder. Group 1 rat received 10 ml/kg of saline solution and served as control. Group 2 mice received sodium salicylate (10 mg/kg (ASA) (standard control) and groups 3, 4 and 5 received 100, 200 and 400mg/kg of *C. millenii* extract respectively per Os (p.o.). Animal response to the heat varies and such changes includes: kicking of hind foot and jumping about, licking of foot, raising the foot, holding the foot tightly to its body or shaking of the foot. The reaction time was recorded 30, 60, 90 and 120 min after the administration of the treatments. The maximum reaction time was fixed at 30 sec to prevent any injury to the tissues of the paws. If the reading exceeds 30 sec, it would be considered as maximum analgesia.

The maximum possible analgesia (MPA) was calculated as follows:

\[
MPA = \frac{\text{Reaction time for treatment} - \text{reaction time for saline}}{30 \text{ sec}} \times 100
\]

2.8 Statistical analysis
Repeated Measures One way ANOVA Analysis using Dunnett’s multiple comparisons post hoc test was performed using GraphPad Prism (version 7.02), San Diego CA, USA, www.graphPad.com) to compare activity between the control groups and rat treated with the test compounds and values were considered significant at p < 0.05 and above. Results were expressed as mean ± SEM [3-7,9].

3. Results & Discussion
3.1 Chemical constituents of essential oil
The yield of the essential oil was 0.026% (v/w), calculated on a dry weight basis. Eleven compounds representing 100% of the total oil contents were identified in *C. millenii* (Table 1). The volatile compounds were displayed in Table 1, along with their percentages and retention indices calculated on HP-5 column. The major constituents of the oil were limonene (19.9%), diallyl disulfide (18.4%), β-caryophyllene (16.6%), linalool (13.4%), nonanal (10.5%) and trans-calamenene (8.5%). The results could not be compared since no data previously existed on the chemical constituents of *C. millenii* oils. However, the chemical compositions and biological activities of essential oils of *C. sebestina* from Nigeria have been reported. The fruit of *C. sebestina* [11] contained 4-pentenylbutanoic acid ester (12.2 %) while phytol was found in the leaf (13.7%) and flower (16.9%). However, (E)-9-octadecene (20.26%), (E)-5-octadecene (18.68%), 9-eicosene (13.99%) and nonyl cyclopropane (12.42%) were the main compounds in the stem bark oil [12].

^1 Elution order on HP-5 column; ^2 Linear retention indices on HP-5 column; ^3 Literature retention indices;

The chemical compositions of essential oils from Cordia plants varied from each other. Although terpene compounds were most common, the identities of these terpenoids differed from each other. On the basis of the main classes of compounds identified in them from literature, the essential oils of Cordia plants may be classified into different group. There are group containing mainly monoterpenic hydrocarbons common to C. curassavica [13], C. globosa [14], those containing sesquiterpenic hydrocarbons as seen in C. verbenacea [15], C. leucocepha [18], C. leucocollaloides [17] and C. multispicata [18], mixture of monoterpenes and sesquiterpenic hydrocarbons prominent in C. globosa [13], C. curassavica [17], C. verbenacea [19], C. multispicata [18], oils containing oxygenated sesquiterpenes such as C. curassavica [17]; oils with large contents of non-terpenes dominated by C. sebestina [11,12] and C. nitida [20].

Moreover, the biological potentials of essential oils of Cordia plants have been published. The stem oil of C. sebestina possessed antioxidant activity [12]. The essential oil of C. globosa displayed antimicrobial activities against Vibrio cholera [13], while C. verbenacea was found to showed fungistatic activity against Candida albicans and C. krasei and antibacterial activity against Staphylococcus aureus, Bacillus cereus, and Escherichia coli 27 [18]. The oil of C. leucocollaloides [17] and C. curassavica [13] exhibited significant larvicidal activity against the third-instar of Aedes aegypti larvae. The oil C. verbenacea inhibited the growth of Staphylococcus aureus ATCC 6538 and Enterococcus faecalis ATCC 29212 [19].

3.2 Anti-inflammatory activity of the essential oil

Edema formation due to carrageenan in the rat paw is biphasic event. The initial phase is attributed to the release of histamine and serotonin. The second phase of edema is due to the release of prostaglandins, protease and lysosome [21,22]. In this study, we evaluated the anti-inflammatory activity of the C. millenii by the carrageenan-induced paw edema. The carrageenan-induced paw edema model is used to screen the anti-inflammatory activity of a drug in the acute phase of inflammation. Edema induced by carrageenan is believed to be biphasic. The first phase (1 h) involves the release of serotonin and histamine and the second phase (> 1 h) is mediated by cyclooxygenase products characterized by release of neutrophils [23]. At the intermediate of the two phases is as a result of kinin release. Continuity between the two phases is provided by kinin [24].

The essential oil of C. millenii in this report at 200 mg/kg significantly (**p < 0.01) inhibited the edema formation in only the first phase. The anti-edematous activity of C. millenii in the first phase could be attributed to the possible suppression of histamine signaling by the mast cell stabilizing effect [24,25] and direct inhibition of histamine H1 receptor and serotonin.

Fig 1: Effect of the essential oils of C. millenii leaves on Carrageenan-induced inflammation. Control, standard and C. millenii represent 1 mL saline solution, 100 mg/kg of diclofenac injection and 1 mL of 100, 200 and 400 mg of C. millenii leaves essential oil respectively.*p< 0.05, **p> 0.01, ***p>0.001 statistically compared to the control.

The other doses were non-significant during the analysis period. Limonene, diallyl disulfide, β-caryophyllene and linalool which are major constituents in the oils of C. millenii are terpenoids with known anti-inflammatory properties. In-vitro study of the anti-inflammatory effects of limonene showed that at low concentration, there is suppression of ROS (Reactive Oxygen species) for eotaxin-stimulated HL-60 clone 15 cells, while at a higher concentrations limonene inhibited some inflammation mediators such as the NF-kB activation [9]. Nitric oxide, PGE2, IL-1β and IL-6 [28]. In addition β-caryophyllene has also been shown to exert inhibition on pro-inflammatory cytokines such as TNF-α, IL-1β, and IL-6 [27].

3.3 Anti-nociceptive activity of the oil

The results of the analgesic effect of the essential oils of C. millenii on hot plate method are presented in Figure 2. The results showed that there was no significant difference on the thermal stimulus in rats treated with normal saline (control) throughout the 120th min observation. In comparison to the saline treated animals, the significant increase in the reaction time to thermal pain was not detectable in both sodium salicylate (standard). However, the observation in 200 mg/kg treated animals is only noted at 120th min with p< 0.05. Rats treated with sodium salicylate exhibited analgesic activity at a slower interval, which began at 30 min (30.0%) and then increased to a maximum of 50% at the 60th min. The MPA value for the essential oils did not show any analgesic effect in the first 30 min after treatment for all doses but the 200 mg/kg showed an increase activity between the 60th min (30%) to the 120th min (45%).
In hot plate test pain induced by thermal stimulus is exact for centrally mediated analgesia and reported to involve opioids [28]. The hot plate test was chosen to analyze a central analgesic activity, because of its sensitivity to strong centrally mediated analgesia and reported to involve opioids [29].

4. Conclusions

It could be seen that the chemical compositions of essential oils from *C. millenii* varied from those of other members in the genus. In addition, the oil of *C. millenii* exhibited moderate anti-inflammatory action while displaying no anti-nociceptive activity at reasonable concentrations when compared with standards.
